

# **MACHINE LEARNING FOR PREDICTING DIABETES MELLITUS**

A project report submitted in partial fulfilment of the  
requirement for the degree of

**Bachelor in Science**  
**In**  
**Computer Science**  
by

Alexander Roque Rodrigues

under the supervision of  
Ashweta Anand Fondekar

**PARVATIBAI CHOWGULE COLLEGE OF ARTS  
& SCIENCE AUTONOMOUS**

June 2019

# Declaration by Candidate

I declare that this project report has been prepared by me and to the best of my knowledge, it has not previously formed the basis for the award of any diploma or degree by any other University.

Alexander Roque Rodrigues  
Student

# Certificate by Supervisor

Certified that the Project Report is a record of work done by the candidate himself/herself/themselves under my guidance during the period of study and that to the best of my knowledge, it has not previously formed the basis of the award of any degree or diploma of any other University.

Ashweta Anand Fondekar  
Project Supervisor

## Abstract

Diabetes Mellitus is a disease that prevents the body from properly expanding the energy stored from the food consumed. The purpose of this project was to select machine learning algorithms that are able to predict or classify a person as diabetic or healthy based on the legacy data. The algorithms compared were KNN Classifier, Logistic Regression, Decision Tree Classifier, Random Forest Classifier, Gradient Boosting Classifier, Support Vector Classifier and the Multi-Layered Perceptron. From all the above the Multi-Layered Perceptron gave an accuracy of prediction on the dataset as 79.70%. To improve the performance of the classifier, I have considered new features deduced from the currently existing feature set and re-trained the classifier on the new dataset that I generated, which is now able to classify the subject as diabetic or healthy with a new accuracy of 85.42%. After selection of the algorithm I further advanced the platform of cluster computing to deploy the algorithm onto and generate predictions in without any human interference and also made the data available to the users via an easy to use web application which gives them access to the observations then stored in the database after being predicted by the algorithm deployed on the nodes.

## 2 Introduction

In recent days, there has been a sharp increase in the cases of diabetes mellitus. Diabetes mellitus is on the rise amongst many people and the rate of contracting this lifestyle disease could be reduced significantly if proper measures and precautions were to be instilled amongst people the number of people can be reduced.

Machine learning is a growing field in computer science. With the development and introduction of many algorithms the prediction and accuracy of the predictions itself has improved substantially. Machine learning and healthcare systems are also becoming increasingly popular in the healthcare sector.

The project encompasses the qualities of Remote Patient Monitoring (RPM)[28] and Clinical Decision Support (CDS)[14]. RPM provides medical facilities that have the ability to transmit patient data to healthcare professionals who might very well be halfway around the world. RPM can monitor blood glucose levels and blood pressure. It is particularly helpful for patients with chronic conditions such as type 2 diabetes, hypertension, or cardiac disease. Data collected and transmitted via PRM can be used by a healthcare professional or a healthcare team to detect medical events such as stroke or heart attack that require immediate and aggressive medical intervention. Data collected may be used as part of a research project or health study. RPM is a life-saving system for patients in remote areas who cannot access face-to-face health care. CDS analyzes data from clinical and administrative systems. The aim is to assist

healthcare providers in making informed clinical decisions. Data available can provide information to medical professions who are preparing diagnoses or predicting medical conditions like drug interactions and reactions. CDS tools filter information to assist healthcare professionals in caring for individual clients.

Cluster computing or High-Performance computing frameworks is a form of computing in which bunch of computers (often called nodes) that are connected through a LAN (local area network) so that, they behave like a single machine. A computer cluster help to solve complex operations more efficiently with much faster processing speed, better data integrity than a single computer and they are mostly used for critical applications.

## **3 Objective**

### **3.1 Existing System**

Currently, there exist no integrated systems for predicting diabetes. There are however multitudes of researches being carried out on diabetic patient and looking for newer traits that can help predict the onset of the sickness.

### **3.2 Proposed System**

The objective of this project is to select an algorithm that is capable of classifying a healthy person from a diabetic person. After which the selected algorithm will be deployed to a group of computers which will help us expand the computing capabilities further than a single computer. The model should then write to a database than can be queried to present data to the users who will interface the said program.

## 4 Project Rationale

Diabetes is a chronic disease that occurs either when the pancreas does not produce enough insulin or when the body cannot effectively use the insulin it produces. Insulin is a hormone that regulates blood sugar. Hyperglycemia, or raised blood sugar, is a common effect of uncontrolled diabetes and over time leads to serious damage to many of the body's systems, especially the nerves and blood vessels.

Taking a look at the number of people with diabetes, the count has risen from 108 million in 1980 to 422 million in 2014. The global prevalence of diabetes among adults over 18 years of age has risen from 4.7% in 1980 to 8.5% in 2014. Diabetes prevalence has been rising more rapidly in middle-income and low-income countries. Diabetes as a disease is a major cause of blindness, kidney failure, heart attacks, stroke and lower limb amputation amongst those who recognise the fatal disease late in life. In 2016, an estimated 1.6 million deaths were directly caused by diabetes. Another 2.2 million deaths were attributable to high blood glucose in 2012. Almost half of all deaths attributable to high blood glucose occur before the age of 70 years. WHO estimates that diabetes was the seventh leading cause of death in 2016. A healthy diet, regular physical activity, maintaining a normal body weight and avoiding tobacco use are ways to prevent or delay the onset of type 2 diabetes. Diabetes can be treated and its consequences avoided or delayed with diet, physical activity, medication and regular screening and treatment for complications. In 2014, 8.5% of adults aged 18 years and older had diabetes. In 2016, diabetes was the direct cause of 1.6 million deaths and in 2012 high blood glucose was the cause of another 2.2 million deaths.

Diabetes patients are segregated into types. Type 1 diabetes is characterized by deficient insulin production and requires daily administration of insulin. The cause of type 1 diabetes is not known and it is not preventable with current knowledge. A person with type 1 diabetes may have symptoms like excessive excretion of urine, thirst, constant hunger, weight loss, vision changes, and fatigue. These symptoms may occur suddenly.

Type 2 diabetes results from the body's ineffective use of insulin. Type 2 diabetes comprises the majority of people with diabetes around the world, and is largely the result of excess body weight and physical inactivity. Symptoms may be similar to those of type 1 diabetes, but are often less marked. As a result, the disease may be diagnosed several years after onset, once complications have already arisen.

Until recently, this type of diabetes was seen only in adults but it is now also occurring increasingly frequently in children.

Gestational diabetes is another type of diabetes where hyperglycemia with blood glucose values above normal but below those diagnostic of diabetes, occurring during pregnancy. Women with gestational diabetes are at an increased risk of complications

during pregnancy and at delivery. They and their children are also at increased risk of type 2 diabetes in the future. Gestational diabetes is diagnosed through prenatal screening, rather than through reported symptoms.

Untreated diabetes can damage the heart, blood vessels, eyes, kidneys, and nerves. Adults with diabetes have a two- to three-fold increased risk of heart attacks and strokes. Combined with reduced blood flow, neuropathy (nerve damage) in the feet increases the chance of foot ulcers, infection and eventual need for limb amputation. Diabetic retinopathy is an important cause of blindness, and occurs as a result of long-term accumulated damage to the small blood vessels in the retina. 2.6% of global blindness can be attributed to diabetes. Diabetes is among the leading causes of kidney failure.

Early diagnosis can be accomplished through relatively inexpensive testing of blood sugar. Treatment of diabetes involves diet and physical activity along with lowering blood glucose and the levels of other known risk factors that damage blood vessels. Tobacco use cessation is also important to avoid complications.

## 5 Review of Literature

For the study I have chosen to perform a comparative study between the K Nearest Neighbours algorithm, Logistic Regression, Decision Tree Classifier, Random Forest Classifier, Gradient Boosting Classifier, Support Vector Machine and finally a Multi Layered Perceptron for the classifier groups.

K Nearest Neighbours, is a supervised machine learning algorithm and relies on labeled input data to learn a function that produces an appropriate output when given new unlabeled data. Supervised machine learning algorithms are used to solve classification or regression problems. A classification problem has a discrete value as its output. Unlike supervised learning that tries to learn a function that will allow us to make predictions given some new unlabeled data, unsupervised learning tries to learn the basic structure of the data to give us more insight into the data. The KNN algorithm assumes that similar things exist in close proximity. In other words, similar things are near to each other. The advantages of the KNN algorithm include the reasons that the algorithm is simple and easy to implement, no need to build a model, tune several parameters, or make additional assumptions and furthermore can be used for classification, regression, and search due to its versatile nature. KNN's main disadvantage of becoming significantly slower as the volume of data increases makes it an impractical choice in environments where predictions need to be made rapidly. Moreover, there are faster algorithms that can produce more accurate classification and regression results. However, provided the user has sufficient computing resources to speedily handle the data used to make predictions, KNN can still be useful in solving problems that have solutions that depend on identifying similar objects. An example of this is using the KNN algorithm in recommender systems, an application of KNN-search.

The linear regression model can work well for regression, but fails for classification. The reason for this being that in case of two classes, you could label one of the classes with 0 and the other with 1 and use linear regression. Technically it works and most linear model programs will yield weights for you. But there are a few problems with this approach:

A linear model does not output probabilities, but it treats the classes as numbers (0 and 1) and fits the best hyper-plane (for a single feature, it is a line) that minimizes the distances between the points and the hyperbola. So it simply interpolates between the points, and you cannot interpret it as probabilities. A linear model also extrapolates and gives you values below zero and above one. This is a good sign that there might be a smarter approach to classification. Since the predicted outcome is not a probability, but a linear interpolation between points, there is no meaningful threshold at which you can distinguish one class from the other.

The logistic regression algorithm even if called regression, is a classification method which is based on the probability for a sample to belong to a class. As our probabilities must be continuous in  $\mathbb{R}$  and bounded between  $(0, 1)$ , it's necessary to introduce a threshold function to filter the term  $z$ . The name logistic comes from the decision to use the sigmoid (or logistic) function:

$$\sigma(z) = \frac{1}{1 + e^z}$$

Not all problems can be solved with linear methods. The world is non-linear. It has been observed that tree based models have been able to map non-linearity effectively. Methods like decision trees, random forest, gradient boosting are being popularly used in all kinds of data science problems.

Decision Tree algorithm belongs to the family of supervised learning algorithms. Unlike other supervised learning algorithms, decision tree algorithm can be used for solving regression and classification problems too. The general motive of using Decision Tree is to create a training model which can use to predict class or value of target variables by learning decision rules inferred from prior data (training data). The primary challenge in the decision tree implementation is to identify which attributes do we need to consider as the root node and each level. Decision trees often mimic the human level thinking so it's simple to understand the data and make some good interpretations.

Dividing efficiently based on maximum information gain is key to decision tree classifier. However, in real world with millions of data dividing into pure class is practically not feasible since it may take longer training time and so we stop at points in nodes of tree when fulfilled with certain parameters an example being impurity percentage. Decision tree is classification strategy as opposed to the algorithm for classification. It takes top down approach and uses divide and conquer method to arrive at decision. We can have multiple leaf classes with this approach.

Putting it simply, decision tree is a decision support tool that uses a tree-like graph or model of decisions and their possible consequences, including chance event outcomes, resource costs, and utility. It is one way to display an algorithm that only contains conditional control statements.

A decision tree is a flowchart-like structure in which each internal node represents a "test" on an attribute (e.g. whether a coin flip comes up heads or tails), each branch represents the outcome of the test, and each leaf node represents a class label (decision taken after computing all attributes). The paths from root to leaf represent classification rules. Tree based learning algorithms are considered to be one of the best and mostly used supervised learning methods. Tree based methods empower predictive models with high accuracy, stability and ease of interpretation. Unlike linear models, they map non-linear relationships quite well. They are adaptable at solving any kind

of problem at hand (classification or regression). Decision Tree algorithms are referred to as CART (Classification and Regression Trees).

Decision trees have a natural “if ... then ... else ...” construction that makes it fit easily into a programmatic structure. They also are well suited to categorization problems where attributes or features are systematically checked to determine a final category. For example, a decision tree could be used effectively to determine the species of an animal.

As a result, the decision making tree is one of the more popular classification algorithms being used in Data Mining and Machine Learning. Some examples of applications include: Evaluation of brand expansion opportunities for a business using historical sales data, determination of likely buyers of a product using demographic data to enable targeting of limited advertisement budget, prediction of likelihood of default for applicant borrowers using predictive models generated from historical data, help with prioritization of emergency room patient treatment using a predictive model based on factors such as age, blood pressure, gender, location and severity of pain, and other measurements. Decision trees are also commonly used in operations research, specifically in decision analysis, to help identify a strategy most likely to reach a goal. Owing to their simplicity, tree diagrams have been used in a broad range of industries and disciplines including civil planning, energy, financial, engineering, healthcare, pharmaceutical, education, law, and business.

Decision tree is a type of supervised learning algorithm (having a pre-defined target variable) that is mostly used in classification problems. It works for both categorical and continuous input and output variables. In this technique, we split the population or sample into two or more homogeneous sets (or sub-populations) based on most significant splitter / differentiator in input variables.

Advantages of Decision Tree: Easy to Understand: Decision tree output is very easy to understand even for people from non-analytical background. It does not require any statistical knowledge to read and interpret them. Its graphical representation is very intuitive and users can easily relate their hypothesis.

Useful in Data exploration: Decision tree is one of the fastest way to identify most significant variables and relation between two or more variables. With the help of decision trees, we can create new variables / features that has better power to predict target variable. It can also be used in data exploration stage. For e.g., we are working on a problem where we have information available in hundreds of variables, there decision tree will help to identify most significant variable.

Decision trees implicitly perform variable screening or feature selection.

Decision trees require relatively little effort from users for data preparation. Less data cleaning required: It requires less data cleaning compared to some other modeling techniques. It is not influenced by outliers and missing values to a fair degree.

Data type is not a constraint: It can handle both numerical and categorical variables. Can also handle multi-output problems. Non-Parametric Method: Decision tree is considered to be a non-parametric method. This means that decision trees have no assumptions about the space distribution and the classifier structure.

Non-linear relationships between parameters do not affect tree performance. The number of hyper-parameters to be tuned is almost null.

Disadvantages of Decision Tree: Over fitting: Decision-tree learners can create over-complex trees that do not generalize the data well. This is called overfitting. Over fitting is one of the most practical difficulty for decision tree models. This problem gets solved by setting constraints on model parameters and pruning. Not fit for continuous variables: While working with continuous numerical variables, decision tree loses information, when it categorizes variables in different categories. Decision trees can be unstable because small variations in the data might result in a completely different tree being generated. This is called variance, which needs to be lowered by methods like bagging and boosting. Greedy algorithms cannot guarantee to return the globally optimal decision tree. This can be mitigated by training multiple trees, where the features and samples are randomly sampled with replacement. Decision tree learners create biased trees if some classes dominate. It is therefore recommended to balance the data set prior to fitting with the decision tree. Information gain in a decision tree with categorical variables gives a biased response for attributes with greater no. of categories. Generally, it gives low prediction accuracy for a dataset as compared to other machine learning algorithms. Calculations can become complex when there are many class label.

The random forest is a model made up of many decision trees. Rather than just simply averaging the prediction of trees (which we could call a “forest”), this model uses two key concepts that gives it the name random: Random sampling of training data points when building trees Random subsets of features considered when splitting nodes

When training, each tree in a random forest learns from a random sample of the data points. The samples are drawn with replacement, known as bootstrapping, which means that some samples will be used multiple times in a single tree. The idea is that by training each tree on different samples, although each tree might have high variance with respect to a particular set of the training data, overall, the entire forest will have lower variance but not at the cost of increasing the bias. At test time, predictions are made by averaging the predictions of each decision tree. This procedure of training each individual learner on different bootstrapped subsets of the data and then averaging the predictions is known as bagging, short for bootstrap aggregating.

The random forest combines hundreds or thousands of decision trees, trains each one on a slightly different set of the observations, splitting nodes in each tree considering

a limited number of the features. The final predictions of the random forest are made by averaging the predictions of each individual tree.

Decision tree a model that makes decisions based on a sequence of questions asked about feature values. It has low bias and high variance leading to overfitting the training data. Each decision tree has a factor known as Gini Impurity. The gini impurity of a tree is measure that the decision tree tries to minimize when splitting each node. Represents the probability that a randomly selected sample from a node will be incorrectly classified according to the distribution of samples in the node. In order to make the algorithm more random we also look at a technique called bootstrapping which is sampling random sets of observations with replacement. Random subsets of features comes into play when selecting a random set of the features when considering splits for each node in a decision tree. Random Forest is the ensemble model made of many decision trees using bootstrapping, random subsets of features, and average voting to make predictions. Looking at the Bias-variance trade-off which a core issue in machine learning describing the balance between a model with high flexibility (high variance) that learns the training data very well at the cost of not being able to generalize to new data that is passed to it out of the dataset, and an inflexible model (high bias) that cannot learn the training data. A random forest reduces the variance of a single decision tree leading to better predictions on new data.

Boosting is a method of converting weak learners into strong learners. In boosting, each new tree is a fit on a modified version of the original data set. The gradient boosting algorithm can be most easily explained by first introducing the Ada-Boost Algorithm. The Ada-Boost Algorithm begins by training a decision tree in which each observation is assigned an equal weight. After evaluating the first tree, we increase the weights of those observations that are difficult to classify and lower the weights for those that are easy to classify. The second tree is therefore grown on this weighted data. Here, the idea is to improve upon the predictions of the first tree. Our new model is therefore  $Tree1 + Tree2$ . We then compute the classification error from this new 2-tree ensemble model and grow a third tree to predict the revised residuals. We repeat this process for a specified number of iterations. Subsequent trees help us to classify observations that are not well classified by the previous trees. Predictions of the final ensemble model is therefore the weighted sum of the predictions made by the previous tree models.

Gradient Boosting trains many models in a gradual, additive and sequential manner. The major difference between Ada-Boost and Gradient Boosting Algorithm is how the two algorithms identify the shortcomings of weak learners (eg. decision trees). While the Ada-Boost model identifies the shortcomings by using high weight data points, gradient boosting performs the same by using gradients in the loss function ( $y = ax + b + e$  ,  $e$  needs a special mention as it is the error term). The loss function

is a measure indicating how good are model's coefficients are at fitting the underlying data. A logical understanding of loss function would depend on what we are trying to optimise. For example, if we were to consider that we are trying to predict the sales prices by using a regression, then the loss function would be based off the error between true and predicted house prices. Similarly, if our goal is to classify credit defaults, then the loss function would be a measure of how good our predictive model is at classifying bad loans. One of the biggest motivations of using gradient boosting is that it allows one to optimise a user specified cost function, instead of a loss function that usually offers less control and does not essentially correspond with real world applications.

Hyper-parameter tuning is especially significant for gradient boosting algorithm since they are prone to overfitting. The special process of tuning the number of iterations for an algorithm such as gradient boosting modelling and random forest is called "Early Stopping". Early Stopping performs model optimisation by monitoring the model's performance on a separate test data set and stopping the training procedure once the performance on the test data stops improving beyond a certain number of iterations. It avoids overfitting by attempting to automatically select the inflection point where performance on the test dataset starts to decrease while performance on the training dataset continues to improve as the model starts to overfit. In the context of gradient boosting, early stopping can be based either on an out of bag sample set ("OOB") or cross-validation ("cv"). Like mentioned above, the ideal time to stop training the model is when the validation error has decreased and started to stabilise before it starts increasing due to overfitting.

Gradient boosting involves three quintessential elements. A loss function to be optimized, a weak learner to make predictions and finally, an additive model to add weak learners to minimize the loss function.

Some important terms of gradient boosting algorithm is the loss function. The loss function used depends on the type of problem being solved. It must be differentiable, but many standard loss functions are supported and you can define your own loss function. A benefit of the gradient boosting framework is that a new boosting algorithm does not have to be derived for each loss function that may want to be used, instead, it is a generic enough framework that any differentiable loss function can be used.

Weak Learners, are the decision trees are used as the weak learner in gradient boosting. Specifically regression trees are used that output real values for splits and whose output can be added together, allowing subsequent models outputs to be added and "correct" the residuals in the predictions. Trees are constructed in a greedy manner, choosing the best split points based on purity scores like Gini or to minimize the loss functions values. It is common to constrain the weak learners in specific ways, such as a maximum number of layers, nodes, splits or leaf nodes. This is to ensure that the learners remain weak, but can still be constructed in a greedy manner.

Additive Model is an algorithm wherein trees are added one at a time, and existing trees in the model are not changed. A gradient descent procedure is used to minimize the loss when adding trees. Instead of parameters, we have weak learner sub-models or more specifically decision trees. After calculating the loss, to perform the gradient descent procedure, we must add a tree to the model that reduces the loss (i.e. follow the gradient). We do this by parameterizing the tree, then modify the parameters of the tree and move in the right direction by (reducing the residual loss. Generally this approach is called functional gradient descent or gradient descent with functions. The output for the new tree is then added to the output of the existing sequence of trees in an effort to correct or improve the final output of the model. A fixed number of trees are added or training stops once loss reaches an acceptable level or no longer improves on an external validation dataset.

Moving on we have the SVM. The objective of the support vector machine algorithm is to find a hyper-plane in an N-dimensional space(N being the number of features) that distinctly classifies the data points. To separate the two classes of data points, there are many possible hyperbola that could be chosen. Our objective is to find a plane that has the maximum margin, i.e the maximum distance between data points of both classes. Maximizing the margin distance provides some reinforcement so that future data points can be classified with more confidence. Hyper-planes are decision boundaries that help classify the data points. Data points falling on either side of the hyper-plane can be attributed to different classes. Also, the dimension of the hyper-plane depends upon the number of features. If the number of input features is 2, then the hyper-plane is just a line. If the number of input features is 3, then the hyper-plane becomes a two-dimensional plane. It becomes difficult to imagine when the number of features exceeds 3. Support vectors are data points that are closer to the hyper-plane and influence the position and orientation of the hyper-plane. Using these support vectors, we maximize the margin of the classifier. Deleting the support vectors will change the position of the hyper-plane.

Maximal-Margin Classifier The Maximal-Margin Classifier is a hypothetical classifier that best explains how SVM works in practice. The numeric input variables (x) in your data (the columns) form an n-dimensional space. For example, if you had two input variables, this would form a two-dimensional space.

A hyper-plane is a line that splits the input variable space. In SVM, a hyper-plane is selected to best separate the points in the input variable space by their class, either class 0 or class 1. In two-dimensions one can visualize this as a line and all of the input points can be completely separated by this line. For example:

$$B0 + (B1 * X1) + (B2 * X2) = 0$$

Where the coefficients ( $B1$  and  $B2$ ) that determine the slope of the line and the intercept ( $B0$ ) are found by the learning algorithm, and  $X1$  and  $X2$  are the two input variables.

By plugging in input values into the line equation, it can be calculated, whether a new point is above or below the line.

If the point is above the line, the equation returns a value greater than 0 and the point belongs to the first class (class 0). If below the line, the equation returns a value less than 0 and the point belongs to the second class (class 1). A value close to the line returns a value close to zero and the point may be difficult to classify. If the magnitude of the value is large, the model may have more confidence in the prediction. The distance between the line and the closest data points is referred to as the margin. The best or optimal line that can separate the two classes is the line that has the largest margin. This is called the Maximal-Margin hyper-plane. The margin is calculated as the perpendicular distance from the line to only the closest points. Only these points are relevant in defining the line and in the construction of the classifier. These points are called the support vectors. They support or define the hyper-plane. The hyper-plane is learned from training data using an optimization procedure that maximizes the margin.

**Soft Margin Classifier** In practice, real data is messy and cannot be separated perfectly with a hyper-plane.

The constraint of maximizing the margin of the line that separates the classes must be relaxed. This is often called the soft margin classifier. This change allows some points in the training data to violate the separating line.

A tuning parameter is introduced called simply  $C$  that defines the magnitude of the wiggle allowed across all dimensions. The  $C$  parameter defines the amount of violation of the margin allowed. A  $C=0$  is no violation and we are back to the inflexible Maximal-Margin Classifier described above. The larger the value of  $C$  the more violations of the hyper-plane are permitted.

During the learning of the hyper-plane from data, all training instances that lie within the distance of the margin will affect the placement of the hyper-plane and are referred to as support vectors. And as  $C$  affects the number of instances that are allowed to fall within the margin,  $C$  influences the number of support vectors used by the model.

The smaller the value of  $C$ , the more sensitive the algorithm is to the training data (higher variance and lower bias). The larger the value of  $C$ , the less sensitive the algorithm is to the training data (lower variance and higher bias). A powerful insight is that the linear SVM can be rephrased using the inner product of any two given observations, rather than the observations themselves. The inner product between two vectors is the sum of the multiplication of each pair of input values.

Coming to the last model we have the Multilayered Perceptron. Multilayer Perceptrons, or MLPs for short, are the classical type of neural network.

They are comprised of one or more layers of neurons. Data is fed to the input layer, there may be one or more hidden layers providing levels of abstraction, and predictions are made on the output layer, also called the visible layer.

MLPs are suitable for classification prediction problems where inputs are assigned a class or label.

They are also suitable for regression prediction problems where a real-valued quantity is predicted given a set of inputs. Data is often provided in a tabular format, such as you would see in a CSV file or a spreadsheet.

Multilayered Perceptron are used for:

- Tabular datasets.
- Classification prediction problems.
- Regression prediction problems.
- They are very flexible and can be used generally to learn a mapping from inputs to outputs.

This flexibility allows them to be applied to other types of data. For example, the pixels of an image can be reduced down to one long row of data and fed into a MLP. The words of a document can also be reduced to one long row of data and fed to a MLP. Even the lag observations for a time series prediction problem can be reduced to a long row of data and fed to a MLP.

The field of artificial neural networks is often just called neural networks or multi-layer perceptrons after perhaps the most useful type of neural network. A perceptron is a single neuron model that was a precursor to larger neural networks.

It is a field that investigates how simple models of biological brains can be used to solve difficult computational tasks like the predictive modeling tasks we see in machine learning. The goal is not to create realistic models of the brain, but instead to develop robust algorithms and data structures that we can use to model difficult problems.

The power of neural networks come from their ability to learn the representation in your training data and how to best relate it to the output variable that you want to predict. In this sense neural networks learn a mapping. Mathematically, they are capable of learning any mapping function and have been proven to be a universal approximation algorithm.

The predictive capability of neural networks comes from the hierarchical or multi-layered structure of the networks. The data structure can pick out (learn to represent) features at different scales or resolutions and combine them into higher-order features. For example from lines, to collections of lines to shapes.

Let us take a look at the essential features of MLP's:

- **Neurons** - The building block for neural networks are artificial neurons. These are simple computational units that have weighted input signals and produce an output signal using an activation function.
- **Neuron Weights** - You may be familiar with linear regression, in which case the weights on the inputs are very much like the coefficients used in a regression equation. Weights are often initialized to small random values, such as values in the range 0 to 0.3, although more complex initialization schemes can be used.
- **Activation** - The weighted inputs are summed and passed through an activation function, sometimes called a transfer function. An activation function is a simple mapping of summed weighted input to the output of the neuron. It is called an activation function because it governs the threshold at which the neuron is activated and strength of the output signal. Traditionally non-linear activation functions are used. This allows the network to combine the inputs in more complex ways and in turn provide a richer capability in the functions they can model. Non-linear functions like the logistic also called the sigmoid function were used that output a value between 0 and 1 with an s-shaped distribution, and the hyperbolic tangent function also called tanh that outputs the same distribution over the range -1 to +1. More recently the rectifier activation function has been shown to provide better results.
- **Networks of Neurons** - Neurons are arranged into networks of neurons. A row of neurons is called a layer and one network can have multiple layers. The architecture of the neurons in the network is often called the network topology.
- **Input or Visible Layers** - The bottom layer that takes input from your dataset is called the visible layer, because it is the exposed part of the network. Often a neural network is drawn with a visible layer with one neuron per input value or column in your dataset. These are not neurons as described above, but simply pass the input value through to the next layer.
- **Hidden Layers** - Layers after the input layer are called hidden layers because that are not directly exposed to the input. The simplest network structure is to have a single neuron in the hidden layer that directly outputs the value. Given increases in computing power and efficient libraries, very deep neural networks can be constructed. Deep learning can refer to having many hidden layers in your neural network. They are deep because they would have been unimaginably slow to train historically, but may take seconds or minutes to train using modern techniques and hardware.

- **Output Layer** The final hidden layer is called the output layer and it is responsible for outputting a value or vector of values that correspond to the format required for the problem.
- **Stochastic Gradient Descent** The classical and still preferred training algorithm for neural networks is called stochastic gradient descent. This is where one row of data is exposed to the network at a time as input. The network processes the input upward activating neurons as it goes to finally produce an output value. This is called a forward pass on the network. It is the type of pass that is also used after the network is trained in order to make predictions on new data. The output of the network is compared to the expected output and an error is calculated. This error is then propagated back through the network, one layer at a time, and the weights are updated according to the amount that they contributed to the error. This clever bit of math is called the back-propagation algorithm. The process is repeated for all of the examples in your training data. One of updating the network for the entire training dataset is called an epoch. A network may be trained for tens, hundreds or many thousands of epochs.
- **Weight Updates** - The weights in the network can be updated from the errors calculated for each training example and this is called online learning. It can result in fast but also chaotic changes to the network. Alternatively, the errors can be saved up across all of the training examples and the network can be updated at the end. This is called batch learning and is often more stable. Typically, because datasets are so large and because of computational efficiencies, the size of the batch, the number of examples the network is shown before an update is often reduced to a small number, such as tens or hundreds of examples. The amount that weights are updated is controlled by a configuration parameters called the learning rate. It is also called the step size and controls the step or change made to network weight for a given error. Often small weight sizes are used such as 0.1 or 0.01 or smaller.
- **Momentum** is a term that incorporates the properties from the previous weight update to allow the weights to continue to change in the same direction even when there is less error being calculated. **Learning Rate Decay** is used to decrease the learning rate over epochs to allow the network to make large changes to the weights at the beginning and smaller fine tuning changes later in the training schedule.
- **Prediction** - Once a neural network has been trained it can be used to make predictions. The network topology and the final set of weights is all that you need to save from the model. Predictions are made by providing the input to the

network and performing a forward-pass allowing it to generate an output that one can use as a prediction.

Neural networks require the input to be scaled in a consistent way. Re-scaling it to the range between 0 and 1 called normalization. Another popular technique is to standardize it so that the distribution of each column has the mean of zero and the standard deviation of 1. Scaling also applies to image pixel data. Data such as words can be converted to integers, such as the popularity rank of the word in the dataset and other encoding techniques.

A distributed computer system consists of multiple software components that are on multiple computers, but run as a single system. The computers that are in a distributed system can be physically close together and connected by a local network, or they can be geographically distant and connected by a wide area network. A distributed system can consist of any number of possible configurations, such as mainframes, personal computers, workstations, minicomputers, and so on. The goal of distributed computing is to make such a network work as a single computer.

After selecting one algorithm we look to deploy one onto distributed systems model[20], since they offer many benefits over centralized systems, including the following:

- Scalability - The system can easily be expanded by adding more machines as needed.
- Redundancy - Several machines can provide the same services, so if one is unavailable, work does not stop. Additionally, because many smaller machines can be used, this redundancy does not need to be prohibitively expensive.

Distributed computing systems can run on hardware that is provided by many vendors, and can use a variety of standards-based software components. Such systems are independent of the underlying software. They can run on various operating systems, and can use various communications protocols. Some hardware might use UNIX or Linux as the operating system, while other hardware might use Windows operating systems. For inter-machine communications, this hardware can use SNA or TCP/IP on Ethernet or Token Ring.

## 6 Software Requirements

The main function of this project is to enable the doctors to advise their patients with the help of the prediction software. The system should be accessible to the patient as well as the doctor, therefore it should have a web interface for the two parties to interact with.

### 6.1 Functionalities for Doctors

As an owner of a doctors account a doctor should be able to:

- Add new observations for the machine learning algorithm to predict.
- Analyse the patients previous records.
- Have a dashboard for patient performance monitoring.

### 6.2 Functionalities for Patients

As the patient, one should be able to:

- Should be able to see the predicted risk of developing diabetes.
- Should be able to view historic data.

### 6.3 Functionalities for Master Nodes

As the master nodes:

- Control chunk size.
- Remotely update the slave nodes.
- Check the status of nodes.
- Control the SQL database.

### 6.4 Functionalities for Slave Nodes

- Should have the machine learning algorithm tuned as per specifications.
- Remote update should be possible.
- Remote access should be possible.

## 7 Hardware Requirements

### 7.1 Raspberry Pi

According to [raspberrypi.org](http://raspberrypi.org)[31], the Raspberry Pi 3 Model B is the earliest model of the third-generation Raspberry Pi. It replaced the Raspberry Pi 2 Model B in February 2016. Some of the key features of this single board computer or SBC are:

- Quad Core 1.2GHz Broadcom BCM2837 64bit CPU.
- 1GB RAM.
- BCM43438 wireless LAN and Bluetooth Low Energy (BLE) on board.
- 100 Base Ethernet.
- 40-pin extended GPIO.
- 4 USB 2 ports.
- Full size HDMI.
- Micro SD port for loading the operating system and storing data.

In this project I will be using 3 Raspberry Pi's to implement a cluster and deploy the machine learning algorithm on.

### 7.2 Switch

A network switch was used in the project to make up for the lack of ethernet ports available on the router.

### 7.3 Router

A router is required to assign internet protocol addresses to the nodes using dynamic host control protocol (DHCP). The router also is responsible for displaying the nodes connected to the network thereby displaying host names and making it more easier to capture the addresses of each node.

### 7.4 Master Node

The master node is assigned the task of managing the the slave nodes connected to the network. The master node and the slave nodes should be connected to the same database to run and execute queries. The master node shall also be assigned with the task of killing a particular process or shutting down a particular node if required.

## **7.5 Slave Node**

The slave nodes are to be configured with the selected algorithm and are the most vital part of the structure. The slave nodes will be responsible for receiving instructions from the master node and will be responsible for learning from the dataset and then can generate predicted outcomes for the patient records received from the master.

## **7.6 Database**

The database will store all the records for the patients and doctors. The database is a SQL database that will not be subjected to a change in the database schema structure for consistency.

## **7.7 Web Server**

The web server provides an interface for the doctor and the patients to read the predictions and legacy data of the patient from the website.

## 8 Technology Stack

### 8.1 Python

#### 8.1.1 Pandas

Pandas, is a library that is required for loading the comma separated value file into python. Pandas is a package for data manipulation and analysis. In particular, it offers data structures and operations for manipulating numerical tables and time series.[2]

#### 8.1.2 Sklearn

Scikit-learn is a free software machine learning library for the Python programming language. It features various classification, regression and clustering algorithms including support vector machines, random forests, gradient boosting, k-means and DBSCAN, and is designed to inter-operate with the Python numerical and scientific libraries NumPy and SciPy.[3]

#### 8.1.3 Numpy

NumPy is a library for the Python programming language, adding support for large, multi-dimensional arrays and matrices, along with a large collection of high-level mathematical functions to operate on these arrays. NumPy is open-source software and has many contributors.[5]

#### 8.1.4 Itertools

The itertools module standardizes a core set of fast, memory efficient tools that are useful by themselves or in combination. Together, they form an “iterator algebra” making it possible to construct specialized tools succinctly and efficiently in pure Python.[1]

### 8.2 MYSQL

MySQL is an open-source relational database management system. MySQL is free and open-source software under the terms of the GNU General Public License, and is also available under a variety of proprietary licenses. MySQL was owned and sponsored by the Swedish company MySQL AB, which was bought by Sun Microsystems (now Oracle Corporation). MySQL is a component of the LAMP web application software stack (and others), which is an acronym for Linux, Apache, MySQL, Perl/PHP/Python. MySQL is used by many database-driven web applications, including Drupal, Joomla, phpBB, and WordPress. MySQL is also used by many popular websites, including Facebook, Flickr, MediaWiki, Twitter and YouTube.[4]

## 8.3 Apache Web Server

The Apache HTTP Server, colloquially called Apache, is free and open-source cross-platform web server software, released under the terms of Apache License 2.0. Apache is developed and maintained by an open community of developers under the auspices of the Apache Software Foundation. The vast majority of Apache HTTP Server instances run on a Linux distribution, but current versions also run on Microsoft Windows and a wide variety of Unix-like systems. Past versions also ran on OpenVMS, NetWare, OS/2 and other operating systems, including ports to mainframes.[29]

## 8.4 PHP

PHP is a general-purpose programming language originally designed for web development. PHP originally stood for Personal Home Page, but it now stands for the recursive initialism PHP: Hypertext Preprocessor. PHP code may be executed with a command line interface (CLI), embedded into HTML code, or used in combination with various web template systems, web content management systems, and web frameworks. PHP code is usually processed by a PHP interpreter implemented as a module in a web server or as a Common Gateway Interface (CGI) executable. The web server outputs the results of the interpreted and executed PHP code, which may be any type of data, such as generated HTML code or binary image data. PHP can be used for many programming tasks outside of the web context, such as standalone graphical applications and robotic drone control.[35]

## 8.5 AJAX

Ajax is a set of web development techniques using many web technologies on the client side to create asynchronous web applications. With Ajax, web applications can send and retrieve data from a server asynchronously (in the background) without interfering with the display and behavior of the existing page. By decoupling the data interchange layer from the presentation layer, Ajax allows web pages and, by extension, web applications, to change content dynamically without the need to reload the entire page.[30]

Ajax is not a single technology, but rather a group of technologies. HTML and CSS can be used in combination to mark up and style information. The webpage can then be modified by JavaScript to dynamically display—and allow the user to interact with—the new information. The built-in XMLHttpRequest object, or since 2017 the new "fetch()" function within JavaScript, is commonly used to execute Ajax on web pages allowing websites to load content onto the screen without refreshing the page. Ajax is not a new technology, or different language, just existing technologies used in

new ways.

## **8.6 GitHub**

GitHub is a global company that provides hosting for software development version control using Git. It offers all of the distributed version control and source code management (SCM) functionality of Git as well as adding its own features. It provides access control and several collaboration features such as bug tracking, feature requests, task management, and wikis for every project.[16]

## **8.7 SSH**

Secure Shell is a cryptography network protocol for operating network services securely over an unsecured network. Typical applications include remote command-line, login, and remote command execution, but any network service can be secured with SSH. The SSH is used to communicate between the master and slave nodes.[44]

## 9 Exploratory Data Analysis

The dataset used for this project is from the UCI Machine learning repository and can be found at their respective website. Table 5 is an outcome of the accuracy of the algorithms subjected to train and 6 is the accuracy obtained from the predicted outcomes for given sets of patients.

Firstly, I began the experiment by examining the amount of people that were recorded by the dataset. We can see that the dataset contains a total of 768 observations. We can see that 268 people are healthy, while the rest of the 500 subjects are diabetic. If converted to percentage, 65.1% of the subjects are healthy and 34.9% of subjects are diabetic.

To proceed with the exploratory data analysis, we can examine the missing values in the dataset. We can see that the dataset has multiple missing values across the columns of the dataset. Plotting of box-plots reveals that the dataset has multiple outliers. To replace these missing values with values to make the predictions more accurate we need to understand the relation of the data to the target variable. To get an understanding we can use the table 9 for clarity on the correlation of values.

To fill the missing values in the dataset we have to consider each of the attributes. For example in the insulin parameter, I have observed that the median value for diabetic people is 169.50 muU/ml, while for the section of healthy participants the median insulin value is recorded at 102.50 muU/ml. Likewise, I carried out the observations on the other attributes of the dataset to fill the missing values via the median of healthy subjects for the healthy subjects whose insulin record is missing and diabetic insulin median for the subjects that are diabetic and do not have values in the columns.

In order to generate new values for the dataset to render more accurate outcomes we look at scatter-plots for our attributes. An example would be the Glucose vs Age scatter-plot. According to the scatter plot of glucose to age we can see that higher glucose value with increase in age, depicts the glucose level of a diabetic person.

## 10 Results

After completing the Exploratory Data Analysis stage and putting the selected model through the k fold verification test we get the following results.

Fold	Precision	F1 Score	Accuracy	Recall	ROC-AUC Curve
1	0.811	0.804	0.864	0.796	0.908
2	0.787	0.733	0.825	0.685	0.896
3	0.841	0.755	0.844	0.685	0.902
4	0.820	0.796	0.863	0.774	0.920
5	0.783	0.832	0.876	0.887	0.933
mean	0.809	0.784	0.854	0.765	0.912
std	0.021	0.035	0.018	0.076	0.013

Table 1: MLP 5 fold verification.

The algorithm is now capable of generating predictions with 85.41% accuracy. A confusion matrix for the same is illustrated below.

Confusion Matrix			
Real	0	<b>451</b>	<b>49</b>
	1	<b>63</b>	<b>205</b>
		0	1
	Predicted		

Table 2: Confusion Matrix for Model.

Table 2 shows the segregation of the correct and incorrect predictions.

Metrics	
F1 Score	0.7854
Recall	0.7649
Precision	0.8071
Accuracy	0.8542

Table 3: Model Performance Metrics.

## 11 Future Scope

## 12 Tables

Column Name	Description
Pregnancies	Number of times pregnant.
Glucose	Plasma glucose concentration a 2 hours in an oral glucose tolerance test.
Blood Pressure	Diastolic blood pressure (mm Hg)
Skin Thickness	Triceps skin fold thickness (mm)
Insulin	2-Hour serum insulin (muU/ml)
Body Mass Index	Body mass index (weight in kg/(height in m) <sup>2</sup> )
Diabetes Pedigree Function	Diabetes pedigree function
Age	Age (years)
Outcome	Class variable (0 or 1) 268 of 768 are 1, the others are 0

## 13 Appendix I

### 13.1 K Nearest Neighbours

```
1 class sklearn.neighbors.KNeighborsClassifier(n_neighbors=5, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)
```

### 13.2 Logistic Regression

```
1 class sklearn.linear_model.LogisticRegression(penalty='l2', dual=False, tol=0.0001, C=1.0, fit_intercept=True, intercept_scaling=1, class_weight=None, random_state=None, solver='lbfgs', max_iter=100, multi_class='auto', verbose=0, warm_start=False, n_jobs=None, l1_ratio=None)
```

### 13.3 Decision Tree

```
1 class sklearn.tree.DecisionTreeClassifier(criterion='gini', splitter='best', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None, random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, class_weight=None, presort='deprecated', ccp_alpha=0.0)
```

### 13.4 Random Forest Classifier

```
1 class sklearn.ensemble.RandomForestClassifier(n_estimators=100, criterion='gini', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto', max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, bootstrap=True, oob_score=False, n_jobs=None, random_state=None, verbose=0, warm_start=False, class_weight=None, ccp_alpha=0.0, max_samples=None)
```

### 13.5 Gradient Boosting

```
1 class sklearn.ensemble.GradientBoostingClassifier(loss='deviance', learning_rate=0.1, n_estimators=100, subsample=1.0, criterion='friedman_mse', min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_depth=3, min_impurity_decrease=0.0, min_impurity_split=None, init=None, random_state=None, max_features=None, verbose=0, max_leaf_nodes=None, warm_start=False, presort='deprecated', validation_fraction=0.1, n_iter_no_change=None, tol=0.0001, ccp_alpha=0.0)
```

## 13.6 Multi Layered Perceptron

```
1 class sklearn.neural_network.MLPClassifier(hidden_layer_sizes=(100, ),
      activation='relu', solver='adam', alpha=0.0001, batch_size='auto',
      learning_rate='constant', learning_rate_init=0.001, power_t
      =0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001,
      verbose=False, warm_start=False, momentum=0.9, nesterovs_momentum=
      True, early_stopping=False, validation_fraction=0.1, beta_1=0.9,
      beta_2=0.999, epsilon=1e-08, n_iter_no_change=10, max_fun=15000)
```

## 13.7 SVM

```
1 class sklearn.svm.SVC(C=1.0, kernel='rbf', degree=3, gamma='scale',
      coef0=0.0, shrinking=True, probability=False, tol=0.001,
      cache_size=200, class_weight=None, verbose=False, max_iter=-1,
      decision_function_shape='ovr', break_ties=False, random_state=None
      )
```

## 13.8 Standard Scaler

```
1 sklearn.preprocessing.StandardScaler(copy=True, with_mean=True,
      with_std=True)
```

## 13.9 Label Encoder

```
1 sklearn.preprocessing.LabelEncoder
```

## 14 Appendix II
